The background of the slide is a dense molecular simulation. At the top, a layer of water molecules is shown in a stick representation, with oxygen atoms in red and hydrogen atoms in white. Below this, a large protein molecule is depicted in a semi-transparent grey surface representation. The protein's surface is decorated with numerous red and blue patches, representing electrostatic potential maps. A few small molecules, possibly ligands or substrates, are visible in stick representation near the protein's surface. The overall scene is set against a black background, highlighting the complex molecular structure and its interaction with the surrounding water.

Allosteric inter-domain signalling controls
SHIP2 phosphatase activity.

SHIP2 bound to substrate

The catalytic center

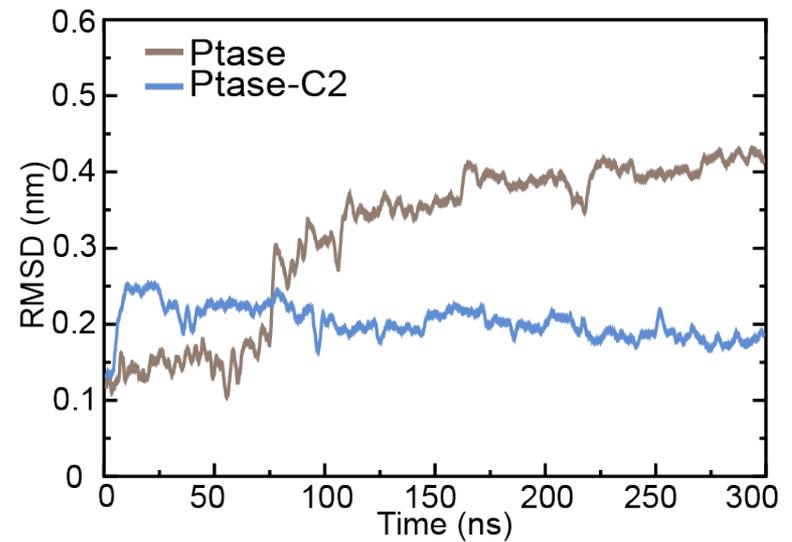

The C2 domain stabilizes substrate

IP₄

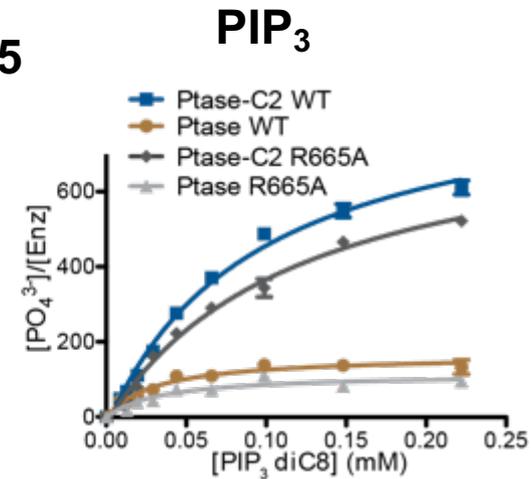

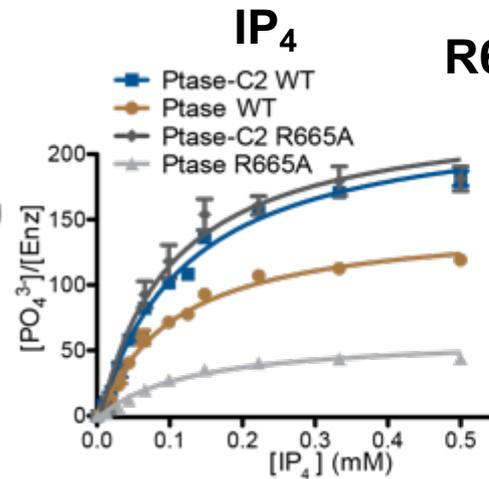

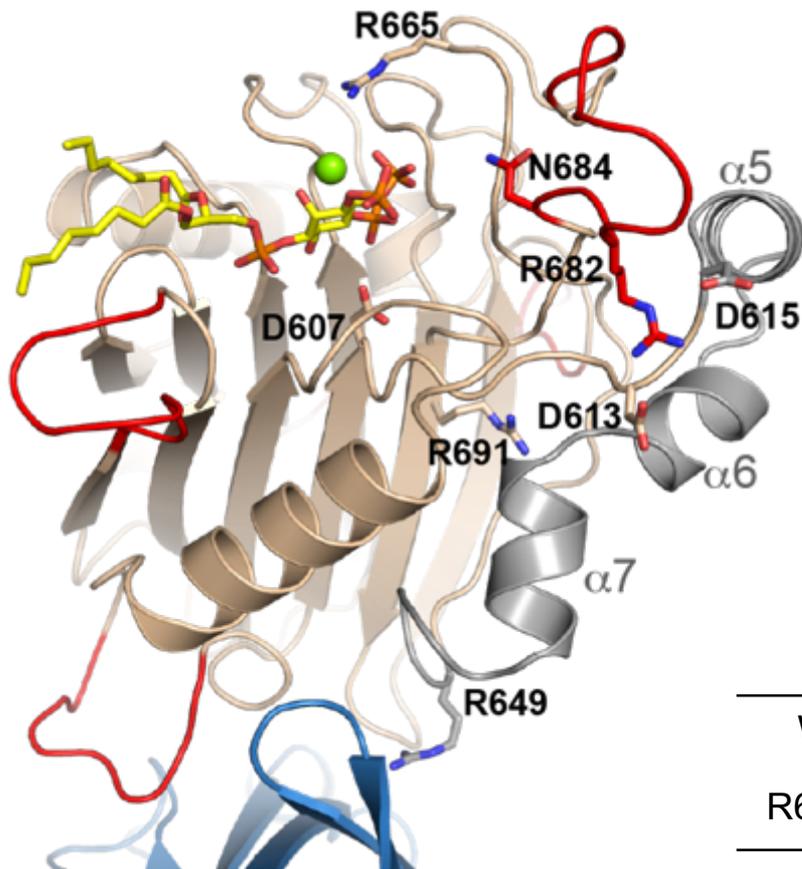

PIP₃

Summary

- C2 domain communicates via hydrophobic interface (F593, L597) to PIP₃
- C2 domain communicates via polar contact (R649) to IP₄
- The “polar path” leads via helices α 5-7 to loop 4 and affects its dynamics
- C2 domain has overall stabilizing effect on active site
